194.025 Introduction to Machine Learning Assignment 3: Regression & Gradient Descent

Welcome to the third assignment of our course **Introduction to Machine Learning**. You will be able to earn up to a total of 10 points. Please read all descriptions carefully to get a full picture of what you have to do.

Remark: Some code cells are put to read-only. Please execute them regardless as they contain important code. You can run a jupyter cell by pressing SHIFT + ENTER, or by pressing the play button on top (in the row where you can find the save button). Cells where you have to implement code contain the comment # YOUR CODE HERE followed by raise NotImplementedError. Simply remove the raise NotImplementedErrorand insert your code.

Some other code cells start with the comment # hidden tests .... Please do not change them in any way as they are used to grade the tasks after your submission.

## 0.1 Implement Gradient Descent for Linear Regression (4 Points)

Implement the algorithm on the slide titled 'Gradient Descent' of the 'Basic Algorithms I' slides.

Ensure that you implement the algorithm using exactly the interface described below.

def gradient\_descent\_linear\_regression(X, y, initial\_w, learning\_rate, epochs)

#### Note:

- To be on the safe side with our auto grading tool, please do not start your names for variables, functions, etc. with solution\_
- Be careful about integer/ float division in python

```
[216]: import numpy as np import numpy.linalg as la import matplotlib.pyplot as plt
```

```
[217]: | # a data sample without noise to toy around, you may use different data
       X = np.linspace(10, 20, 50)
       y = 2.5 * X + 4.0
[231]: def gradient_descent_linear_regression(X, y, initial_w, learning_rate, epochs):
           X: 1d numpy array containing floats
           y: 1d numpy array containing floats
           initial_w: 1d numpy array containing exactly two float values [w_0, w_1]
                       that are used to initialize w_0 and w_1
           learning_rate: float
           epochs: int
           expected output: 1d numpy array containing exactly two float values [w_{\perp}0,_{\sqcup}]
        \hookrightarrow w_1
            111
           # YOUR CODE HERE
           raise NotImplementedError()
[232]: # hidden tests - DO NOT CHANGE THIS CELL
       # hidden tests - DO NOT CHANGE THIS CELL
[233]:
      # hidden tests - DO NOT CHANGE THIS CELL
[222]:
       # hidden tests - DO NOT CHANGE THIS CELL
```

### 0.2 Comparison to Closed Form Linear Regression (2 Points)

Luckily, we know that we can compute  $w_1$  and  $w_0$  (more or less) exactly using the 'Closed Form Solution' equalities.

Implement 'Some Python Code' to compute  $w_1$  and  $w_0$  for the data set given in the next cell.

Fix the learning rate for your gradient descent algorithm to learning rate=0.000001

How many epochs do you need to get the parameters right up to an error of 0.1 when starting at initial\_w=np.array([2,12])?

Assign your answer to the variable reply\_number\_of\_epochs

Is this surprising to you?

**Hint 1:** You can check if all values of two arrays a and b are at least x apart with np.allclose(a,b, atol=x, rtol=0)

**Hint 2:** Looping over all values might not be the fastest solution.

```
[223]: X2 = np.array([-1., -0.95918367, -0.91836735, -0.87755102, -0.83673469, -0.

## 0.3 Polynomial Regression (4 Points)

Implement polynomial regression for one-dimensional input, but arbitrary degree, as described on the slide 'What About Polynomial Regression, then?!?'. That is, the user of your method should be able to specify the degree of the polynomial to fit as a parameter. Note that a polynomial of degree p has p+1 entries in the vector  $\mathbf{w}$ . The polynomial should look as follows:

$$h(x) = \sum_{k=0}^{p} w_k \cdot x^k \ .$$

Also implement the function that, given a weight array np.array([w\_0, w\_1, ..., w\_p]) can compute the function values of the corresponding polynomial.

Ensure that you implement the algorithm using exactly the interface described below.

```
[189]: import numpy as np
       import numpy.linalg as la
[226]: def poly_regression_fit(X, y, p):
           X: 1d numpy array containing floats
           y: 1d numpy array containing floats
           p: a nonnegative integer, giving the degree of the polynomial
           expected output: 1d numpy array containing the float values [w_0, w_1, ..., __
        \hookrightarrow w_p
           111
           # YOUR CODE HERE
           raise NotImplementedError()
[227]: def poly_regression_transform(X, w):
           111
           X: 1d numpy array containing floats
           w: 1d numpy array containing the float values [w_0, w_1, \ldots, w_p]
           expected output: 1d numpy array, same shape as X, containing function values
           # YOUR CODE HERE
           raise NotImplementedError()
